Preface

*"Valid, reliable, timely, culturally relevant and internationally comparable data form the basis for policy and programme development, implementation, monitoring and evaluation"*¹

It is generally accepted that the only justifiable way to deal with development, both theoretically and empirically, is by following the human approach. This implies, *inter alia*, that development is for the sake of the people; that it includes all people in their integral humanity; and that people participate in development decisions and activities that affect their lives.

The involvement of the Development Bank of Southern Africa (DBSA) in the generation of demographic information is a derivative of the Bank's recognition of the indispensable value of information as a resource in the development process.

In order to ensure that timely information on the size, structure and distribution of South Africa's population is available, DBSA's Centre for Policy and Information (CPI) has for some time been engaged in the creation of a demographic information base with the primary aim of catering for the Bank's own information needs. In the creation of this information base, use is made of the results of official population censuses, other secondary sources in which the census results were adjusted, as well as CPI's own estimates based on recognised statistical and demographic techniques.

In socio-economic planning for development, not only the present situation is taken into account, but also the extent to which past and present trends are likely to continue. The same applies to expected population trends. This report is published on demand. Its purpose is to provide a quantitative exposition of the size, structure and distribution of the South African population, and it is directed at especially those persons requiring detailed information on the demography of this country. Since CPI also conducts qualitative research, an in-depth analysis of demography is currently being made with the intention to supplement this quantitative presentation with a qualitative analysis.

This document does not purport to provide an exhaustive list of ramifications of the population question, whether good or bad.

Auditors report

The DBSA's updated estimates of the South African Population were produced using standard demographic techniques. While the scenario method employed reduced the problem of lack of accurate baseline data on fertility, mortality and migration, it is not a substitute for accurate baseline population size and their distribution by province, rural-urban distribution and distribution by magisterial districts. Unfortunately, the accuracy of the baseline data that constituted the input to these projections cannot be guaranteed without an independent national base population. It is, of course, not possible to measure the extent of errors in the data sources that could introduce potential biases in the aggregate and other sub-categories of the population that were produced.

Nevertheless, DBSA's estimates and projections contained in this document will serve useful purposes. Updated estimates and projects that are based on the results from the proposed 1996 national census will certainly carry more authority. The size of any possible variations in the present figures and those expected from the 1996 national census cannot be predicted.

Population of South Africa, updated estimates, 1994

Technical notes

When analysing census figures one of the problems encountered is that the figures for the different years might not be comparable. This might be the result of the establishment of new towns or suburbs after a census was done.

Although there were many instances where the 1980-1985 and 1985-1991 growth rates ranged from exceptionally low to very high, accuracy of the statistics was verified as far as possible. For example, in some cases the population in some towns or suburbs increased from a very low base, resulting in high growth rates, and in others, the boundaries of some towns or suburbs had been redrawn.

DBSA constructed average annual growth rates for each population group per urban or rural area, using various sources and secondary information. The demographic model also incorporates the ratio method and other demographic techniques, which are explained later.

Central Statistical Service (CSS) census figures for 1980, 1985 (adjusted by DBSA) and 1991 (adjusted) were used as a base for the white, Indian and Coloured populations in the demographic model. These figures were analysed and are regarded as reliable.

In the case of Africans, the CSS figures were used as a base in many areas. However, in some townships in the Western Cape, Eastern Cape, KwaZulu/Natal and Gauteng, a new mid-year 1994 population estimate was constructed, based on information obtained from other sources such as local authorities, Eskom, Council for Scientific and Industrial Research (CSIR), the *South African township annual*, *Municipality yearbook*, *Towns of South Africa*, provincial authorities, and DBSA's own database. As is to be expected, the estimates are sometimes inconsistent or show quite a wide variance. In these cases DBSA decided on a consensus mid-year 1994 township/town population per population group, taking into consideration all the relevant information at its disposal.

In the case of the former TBVC states figures were incorporated into the demographic model only after they had been scrutinised and the necessary adjustments had been made by DBSA.

The ratio method was used in estimating the population figures. This method can be described in the following steps:

- The total population for 1994 is calculated by extrapolating the 1991 (DBSA estimated) population with a growth factor of 2,26 per cent per annum up to 1994.
- The percentage distribution of the population per urban or rural area is ascertained for 1980 and 1991.

- The average annual rates of change in the population between 1980 and 1991 are determined for the urban and rural areas (Step 2), and it is assumed that these rates will decrease linearly to zero by the year 2031.
- The mid-term between 1980 and 1991 is determined and, given the assumption in Step 3, a factor is derived which is applied to the average annual rates of change between 1980 and 1991 (Step 3 above) to derive the average annual rates of change for each year between 1991 and 1995.
- The average annual rates of change according to urban or rural area for the respective years are added and the results are multiplied with the percentage distribution of the 1991 population, to derive a preliminary percentage distribution of the population in 1994.
- The percentage distribution of the population for 1994 (Step 5) is applied to the estimated total population for this year (Step 1) to obtain the absolute values per urban and rural areas for 1994.

Descriptive and graphic overview of expected population trends

Introduction

As information on population is primarily concerned with the size, structure and distribution of populations, the contents of this report have been structured along these lines. This section contains a concise description of the main features of the population of South Africa, supplemented by diagrams to facilitate the interpretation of the statistical information. The descriptive and graphic overview is based on the statistical tables presented in Annexure A of the report.

In the diagrams as well as in the tables, the information is presented according to provinces, since apart from considering the salient features of South Africa's total population, the regional characteristics of the population are also of importance. This is especially the case in South Africa owing to the emphasis currently being placed on provincial development.

The production of demographic estimates is a vital demographic activity which has scientific as well as practical relevance. Governmental and private institutions and groups depend heavily on demographic estimates in planning for social and economic development. Over the years, there has been a growing demand for more frequent, up to date and detailed demographic estimates.

At its more sophisticated levels, the preparation of population estimates is a comprehensive demographic enterprise involving the careful consideration of the three major components of population change – fertility, mortality and migration – in relation to the basic age and gender composition of the population in question. Generally, the better one's assumptions regarding

future patterns in fertility, mortality and migration, the more valuable and relevant the estimates.

Population trends

South Africa in an international context

In 1990, the population of South Africa numbered just over 41 million, up from 30,7 million in 1980 (see Figure 1). Over the past decade, the average annual rate of increase in the population has been 2,59 per cent, having tapered off towards the second half of this decade (as reflected in Figure 2). Compared with growth in other developing countries, South Africa's population growth rate is rather high. Indeed, although South Africa is classified as an upper middle income country, it is squarely in the league of low income economies. The latter registered an average annual population growth of 2,8 per cent between 1980 and 1990, if the distorting effects of very low rates in China and India are excluded. In contrast, the lower middle income economies registered an average annual growth rate of 2,3 per cent, while population growth in the upper middle income group averaged only 1,8 per cent per year. Figures 1 and 2 clearly demonstrate that over the past 15 years this trend of high population growth has continued, although to a lesser extent.

Figure 1: Population, 1980-1995

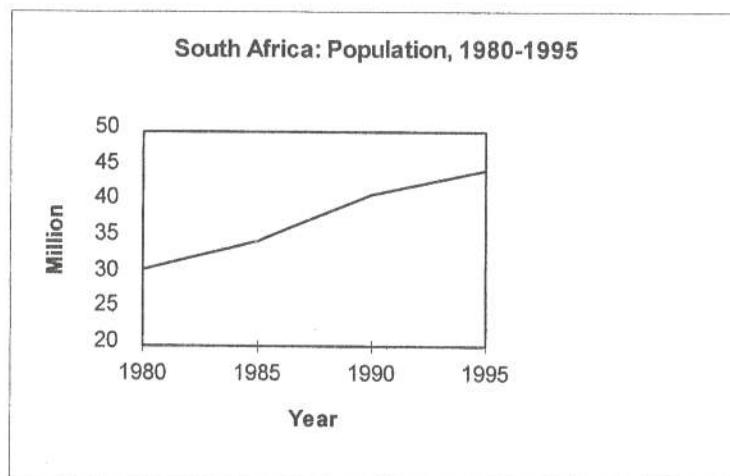

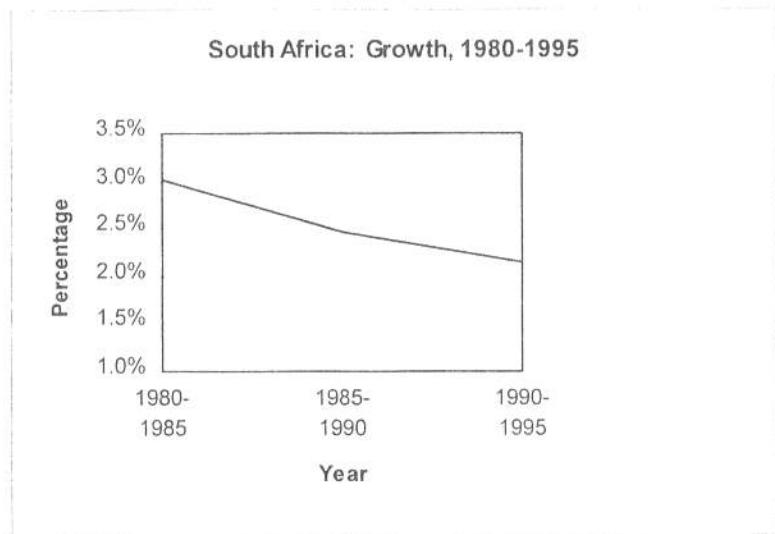

Figure 2: Population growth rates, 1980-1995

Regional population distribution

Spatial distribution

Figures 3, 4 and 5 reflect the spatial distribution of the population per province. This distribution clearly outlines the dominant role of KwaZulu/Natal, whose share of the population is expected to remain at approximately 21 per cent.

Growth in the core areas is likely to result both from migration to the cities by prospective employees, and from natural procreation of the large urban population. Other sizeable concentrations are expected to form in Gauteng, Eastern Cape and Northern Province. Despite the large nodal points in these provinces, they are particularly ill-equipped to provide employment for such large populations.

Figure 3: Population per province, 1980-1995

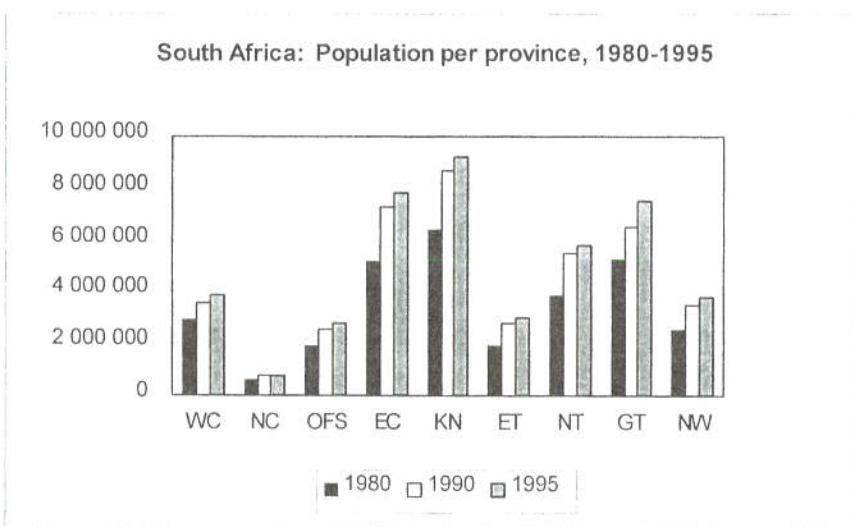

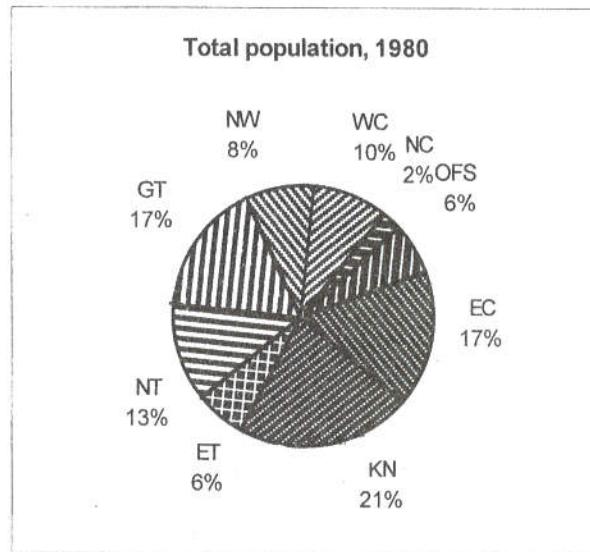

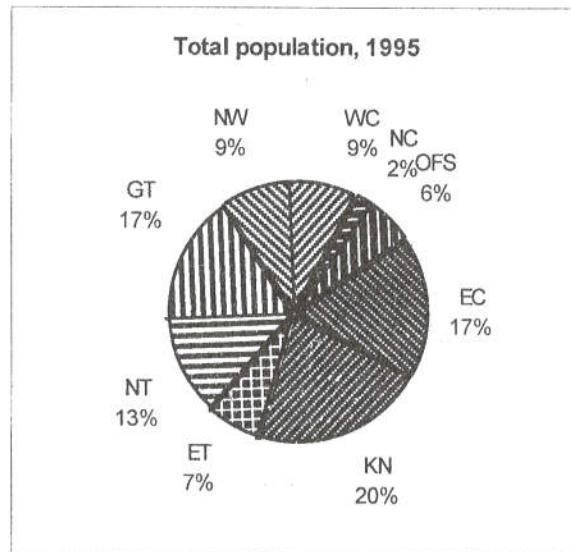

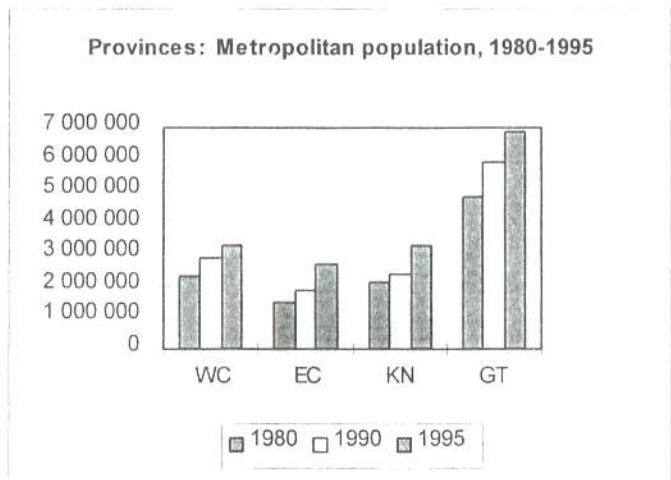

Figure 4: Population per province, 1980**Figure 5: Population per province, 1995**

Level of urbanisation

The size and growth of the population of the four major metropolitan areas in South Africa naturally have a major share in the urbanisation rates of the provinces in which they are situated. Information on the populations of these areas, which comprise about 37 per cent of the total South African population, is visually depicted in Figure 6. Of the four metropolitan areas in South Africa, the largest by far is Gauteng (6,9 million people) followed by the Durban/Pinetown, Western Cape and Port Elizabeth/Uitenhage metropoles with 3,3; 3,2 and 2,7 million people respectively.

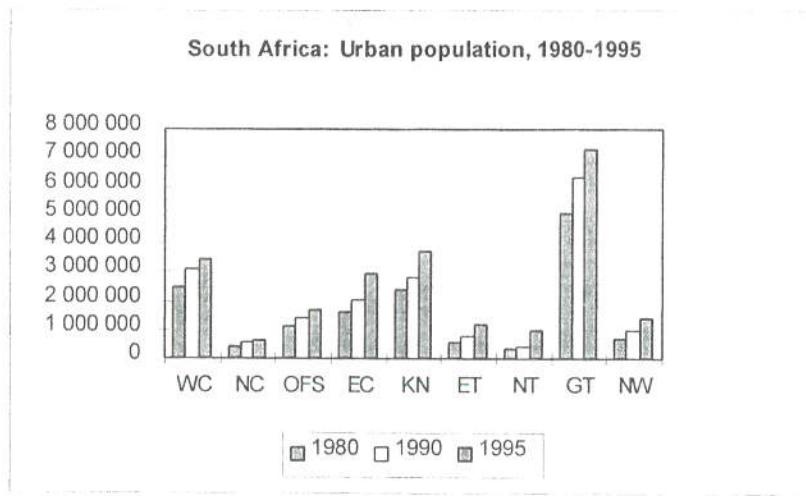

Figure 6: Metropolitan population per province, 1980-1995

The urban population per province for 1980, 1990 and 1995 is indicated in Figure 7. At provincial level, there is a marked difference between the provinces. For example, between 1990 and 1995, Northern and Eastern Province experienced an annual increase of 16,4 and 8,5 per cent respectively in their urban population. Although these rates seem much higher than those of Gauteng, Eastern Cape and KwaZulu/Natal, it must be stressed that they also reflect the growth in the urbanised population from a very low base, the proclamation of new towns and the redrawing of urban boundaries.

The formal level of urbanisation in South Africa during 1995 was about 52 per cent. Furthermore, the average annual rate of increase in the formal urbanised population between 1990-1995 was 4,9 per cent.

Figure 7: Urban population per province, 1980, 1990 and 1995

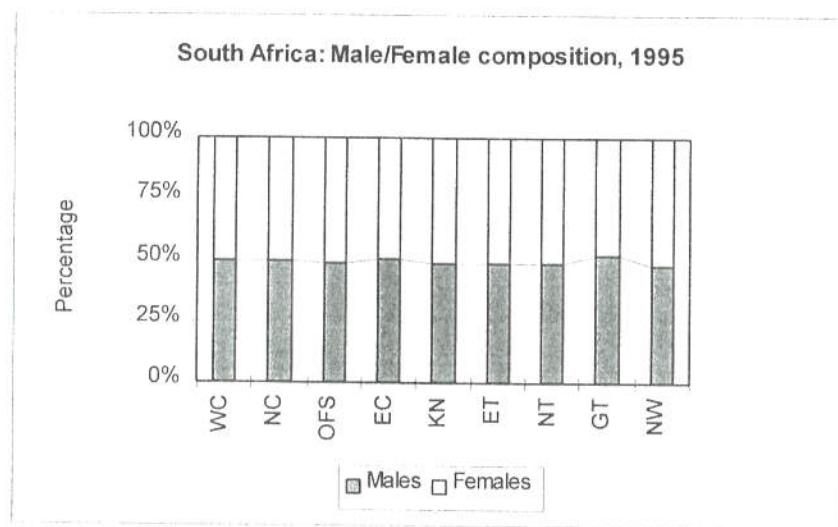

Population structure

The plight of the North West is evident from the gender composition of the population in 1995 (see Figure 8). For example, North West recorded a male to female ratio of 0,909:1 during 1995. This low ratio is merely the result of large-scale migration by

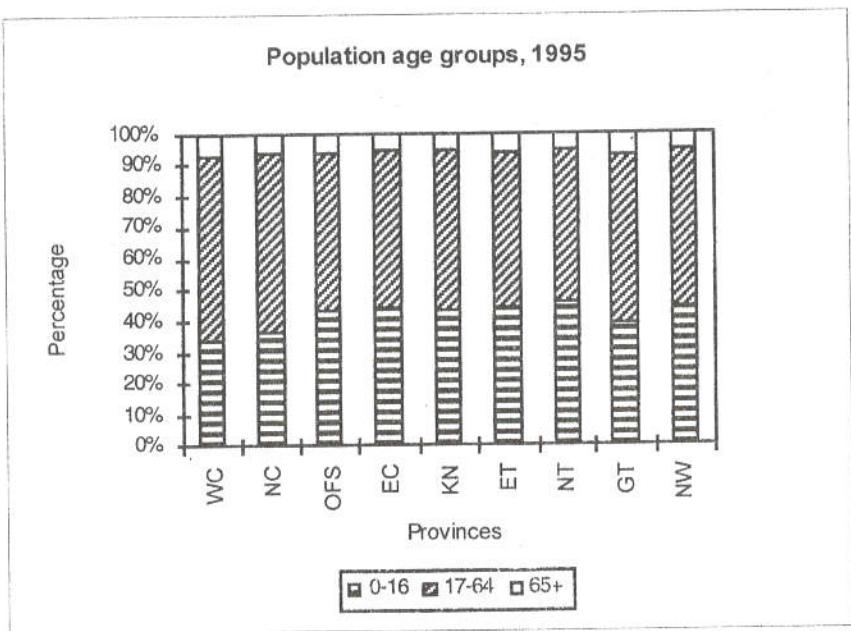

male workers in search of employment in adjacent areas, which is again revealed by gender comparisons in such areas. For instance, Gauteng produced a male to female ratio of 1,095:1, and the Eastern Cape a ratio of 1,031:1, compared with the average of 0,99:1 for South Africa as a whole.

Figure 8: Male and female composition, 1995

A second aspect of population structure deserving attention is the age composition of the population in each province, portrayed in Figure 9. A clustering of adults and younger workers can easily be observed around economic core areas, while the numbers of children proportionally gravitate towards outer peripheral areas. In other words, although a large number of children reside in Gauteng, for example, the largest proportion of children can be found in outer peripheral areas such as the Northern Province. One reason for this trend is that, as adult males migrate, the remaining children form a larger part of the total population. Still, these observations seem to indicate that, despite large increases in numbers, the spatial distribution of the population is likely to remain broadly similar over the next couple of years.

Figure 9: Population age groups, 1995

The population will continue to expand, and the efforts of the population programmes concerning the as yet unborn cannot resolve the problem of providing adequate facilities and access to opportunities to the population in the interim.

Scenarios with regard to population projections, 1990-2020

Introduction

With the South African government's announcement of the Reconstruction and Development Programme (RDP), its possible influence on demographic trends immediately comes to mind. During the past decades South African demographers have developed a number of projection models to show the expected influence of political and economic policy on future population growth. On the whole, these population projections painted a rather gloomy picture of continued high population growth as well as unacceptably slow mortality and fertility decline among the less developed communities in South Africa.

Experience and research in the developing countries of the world have led to the following conclusions:

- Population trends are directly related to economic growth, but the rate of economic growth can be retarded by rapid population growth, specifically through high fertility.
- A vigorous population programme has a strong positive and independent influence on death and birth rates.
- A well-planned and integrated economic and population policy provides the best results in economic growth as well as declining population growth rates.

South Africa has experienced very low and even negative economic growth during the past few decades. Consequently, unemployment and poverty have increased considerably, affecting especially sections of the African population group.

The influence of these socio-economic developments on the demographic trends in the four subgroups of the population was twofold:

On the one hand, the three non-African groups were already well advanced in terms of demographic transition. Increasing economic hardship led to increased fertility control and consequently to lower fertility. On the other hand, a growing stream of Africans departed from the poverty-stricken rural areas and converged on the large industrial cities where many of them ended up in mushrooming squatter towns. The material standard of living of a subsector of Africans declined markedly, in the informal as well as the formal settlements, and this situation slowed down the decline in mortality and fertility. The present infant mortality rate of the total African population is about 60 per 1 000 and informed demographers are of the opinion that this rate will not decline markedly unless the material standard of living of this population is increased significantly. Research has shown that the total fertility rate of Africans has undergone a significant decline since the 1960s, but that the decline has been arrested during the latter part of the 1980s.

When one looks into the demographic future of the four population subgroups, two different scenarios emerge, based on two different directions that economic development may take. On the one hand, economic input may not be sufficient to satisfy the demands of demographic investment (housing, schools, education and infrastructure). On the other hand, there may be a well-integrated economic and population programme. In the first scenario one would expect present demographic trends among the four population subgroups to persist. In the second scenario there will be significant changes in the situation of Africans, while among the demographically advanced non-African groups there will only be specific changes in demographic behaviour.

Let us call the positive economic development that is expected to ensue from the government's RDP "Scenario A", and the less positive development "Scenario B".

Before the two scenarios are examined, a brief discussion of selected demographic indicators among the four population groups is necessary. The information set out below was mostly obtained from the National Demographic and Health Survey which was conducted during the latter half of the 1980s. Vital data from the Central Statistical Service was also used for the calculation of the total fertility rate (TFR) and the infant mortality rate (IMR) among non-Africans.

Table 1: Selected demographic indicators, 1985-1990

	African	Coloured	Indian	White
Total fertility rate	4,6	2,7	2,3	1,7
Contraceptive use (%)	51	72	72	82
% first birth before age 20	47	41	30	17
Infant mortality rate	61	51	17	12
Child mortality rate (1-4)	20	17	4	3
Desired family size among women younger than 25 years	3,0	2,7	2,5	2,7
Unwanted last birth (%)	52	55	53	33
Unwanted last birth among women: – younger than 20 years	59	69	37	40
– 45-49 years	64	65	68	42

The following conclusions can be drawn from the indicators:

- The fertility levels of non-Africans are below or approaching replacement level, and the TFR for Africans has declined by almost one third since the 1960s.
- Contraceptive prevalence is high among non-Africans, and contraceptives are already being used by half of the African couples (in sub-Saharan Africa this is about 10 per cent).
- The incidence of teenage pregnancies is very high amongst Africans and Coloureds. Among whites it is only 17 per cent.

- Infant and child mortality is considerably higher amongst Africans and Coloureds than amongst Indians and whites.
- The desired number of children is low amongst all population groups.
- A considerable number of unplanned pregnancies are found amongst all four population groups, and dissatisfaction with the occurrence of pregnancies is mostly found among younger and older women.
- African women in particular still have larger families than they would want to have, and amongst all groups there is a considerable degree of unhappiness regarding the planning of pregnancies. This situation indicates that the efficiency of contraceptive use can be improved. The relatively high infant and child mortality levels amongst Africans will preclude rapid fertility decline in future. Informed opinion is that the present low material living standards of this group are mainly responsible for the relatively high infant and child mortality rates, and that health programmes alone will not lower these rates significantly. Health programmes are mostly responsible for the decline of the IMR from 300 per 1 000 to about 60 per 1 000, but socio-economic change is needed for further declines.

Scenario development

Scenario A

In this scenario the economic and demographic trends are expected to have a beneficial effect upon each other. In order to establish this advantageous interaction, the following economic-demographic model is relevant:

- In the planning and implementation phases of the economy the population factor is continuously considered. Whenever demographic behaviour becomes a negative factor for economic development, adjustments are made in the variables responsible for these behavioural changes.
- The population policy addresses all aspects of demographic behaviour that could have a negative impact on economic development.
- The following demographic trends will develop in this scenario of high economic growth and a well-integrated population development programme:
 - Amongst Africans and Coloureds the relatively high infant and child mortality rates will start to decline when the living conditions of the deprived sections of these population subgroups begin to change. Only when the majority of families live in healthy environments will infant and child mortality reach the low levels experienced in developed communities. The medical factor alone is of secondary importance in the present living conditions of these two groups. Among whites and Indians mortality

transition has already run its course and economic development will only have a small influence on these trends.

- A population programme which aims to improve mother and child health and family planning by means of educational and motivational campaigns will include, amongst others, the following strategies:
 - The mass media will be used extensively to educate the population on health and reproductive matters.
 - A well-educated and motivated team of health advisers will educate the target population on all aspects of health and reproductive behaviour.
 - Mother and child clinics – fixed and mobile – will be extended to be in close proximity of every community.
 - Specialised family-planning clinics will be established to serve those women who do not need to attend mother and child clinics.
 - Teenage sexuality will receive special attention. Information, education and clinic services will be within reach of all teenagers. These services will be separated from other health care services and facilities.
 - A special programme will cater for the needs of the growing number of men and women who want to terminate their fertility by means of sterilisation.
- The benefit of a vigorous population programme will be that parents and caregivers will be able to raise healthy children. Not only will the individual persons and households benefit by this process, but the country's economy will not be retarded by negative demographic behaviour among large sections of the population.
- Political leaders in the country will have the courage and conviction to support a well-founded population programme actively and to call upon their followers to embrace a low fertility culture.

Scenario B

In this scenario the vicious cycle of poverty and high population growth cannot be broken despite the injection of large amounts of money. This has been the case in many countries of the developing world. Although the reasons for their failure are numerous and specific to each situation or country, a factor they had in common was the high population growth which was either disregarded in the economic plan, or the programme to address population problems proved to be ineffective.

Economic development usually has a slow effect on declining child mortality and on fertility. The whites and Indians, who are at a more advanced stage of demographic transition, will not be significantly influenced by a stagnant economy.

Use of scenarios

The population projections contained in this report do not attempt to simulate entirely objective assumptions regarding fertility, mortality and migration. The purpose of these projections is rather to show, within realistic parameters, what the consequence of demographic trends could be.

It is therefore strongly recommended that

- an ongoing exercise be conducted to measure the actual situation regarding the population *vis à vis* the sets of scenarios. Policy makers would then be in the position to assess their programmes against actual progress and concomitant demographic trends.
- this exercise be repeated within the next five years, for example after the next population census, in order to assess the set of projections for possible errors in the base populations and new trends in demographic processes.

Base population

Africans

For the purpose of this projection a reconstructed population, dated 1987 (Mostert et al., 1987), was employed as the base population. This population differs from the 1991 census population in terms of total population as well as age structure. It was felt that a number of factors made any set of population figures for Africans problematic:

- There was underenumeration during the 1991 census. Although adjustments were made to the enumerated totals based on actual re-enumeration surveys, the areas where only a sample census was taken were not adjusted.
- To date, figures for Transkei, Bophuthatswana and Ciskei have not been finalised. This has made adjustment procedures problematic.
- No actual estimate is available regarding the number of illegal aliens in South Africa.

Given these uncertainties, the author was of the opinion that the population, as reconstructed in 1987, in all likelihood included a fair number of aliens who had made South Africa their residence over the years, and who were added de facto to the "natural population".

Coloureds, Indians and whites

The total population that was used as a base for projections in the case of these subgroups coincides with the 1991 census results. However, a slightly different age structure was employed when the projection was carried out.

Assumptions regarding fertility

The specific fertility assumptions for the projections are depicted in Table 2.

Africans

Scenario A

In accordance with the basic tone of the economic, social and political assumptions, a very optimistic picture of fertility trends is painted in Scenario A. It is assumed that the fertility decline among the African population will continue, but at a higher rate than before. Factors that would promote the realisation of such an optimistic scenario are the following.

- Fertility levels of the African population in South Africa have reached an important threshold level – they are lower than the levels of any African population on the continent.
- There is a strong commitment among political leaders to support a culture of lower fertility.
- A health system which emphasises reproductive health should be supported actively.
- Urbanisation of the population continues and will eventually lead to an urban-dominated value system, with one component being low fertility values.
- Effective mass media programmes exist to promote lower fertility norms and values as well as contraceptive use.
- It should be realised that the fertility assumptions contained in Scenario A are very optimistic in the context of fertility values and patterns on the African continent. However, these assumptions could materialise if the conditions mentioned above are met. Moreover, in the past 30 years a number of demographic transitions have taken place despite the fact that they were initially deemed impossible by international demographers. (In China, for instance, a transition from a very high fertility to a near replacement fertility has occurred.)

Scenario B

The assumptions in Scenario B reflect a less optimistic view of the fertility transition amongst Africans in this country. The underlying hypothesis is that the historic decline in fertility will

continue, but at a lesser rate than in Scenario A. This lesser rate could be ascribed to a lack of total commitment to the issue from the side of political leaders; a health system that becomes strained in an economy unable to deliver to sectors what they require, due in part to a rapid growth in population that requires vast demographic investments; the failure of urban areas to integrate totally the new rural in-migrants with their values of high fertility. (In West Africa, for example, the urbanites have not supplanted their rural value system with an urban set of values in respect of fertility behaviour and this has led to continued high fertility.)

In the context of current fertility patterns and trends in Africa, Scenario B could also be seen as a relatively positive picture. Policy makers should however be aware of the possibility of an outright negative situation if attention is not paid to demographic processes in South Africa.

Coloureds

Over the past 30 years the Coloured population has progressed rapidly from a state of high fertility to a state of moderate fertility. It is assumed that this decrease in fertility will continue, reaching replacement fertility in about 15 years.

Indians

The Indian population has likewise passed rapidly through the demographic transition from high to low fertility. This population could reach replacement fertility within five years.

Whites

At present the white population finds itself below replacement level regarding fertility. In keeping with fertility trends in Western Europe, it is foreseen that the TFR among this subgroup could drop to as low as 1,5.

Table 2: Fertility assumptions

	1990-95	1995-00	2000-05	2005-10	2010-15	2015-20
African (A)	4,3	3,9	3,5	2,9	2,2	2,2
African (B)	4,3	4,1	4,0	3,8	3,7	3,5
Indian	2,3	2,1	2,0	1,9	1,8	1,8
Coloured	2,9	2,6	2,3	2,1	2,0	2,0
White	1,7	1,7	1,6	1,6	1,6	1,5

Assumptions regarding mortality

The specific mortality assumptions for the purpose of the scenarios are depicted in Tables 3 and 4.

Africans

Scenario A

It is assumed that life expectancy and infant mortality levels will improve rapidly. Factors that would be influential in this respect are

- an extended health system
- an improvement in the quality of life of a large section of the population owing to better housing, clean water, availability of electricity, and so on
- improvements in the general standard of living due to, amongst others, a declining unemployment rate.

Scenario B

Historic trends regarding mortality are assumed to continue, albeit at a much reduced rate. For example, if the general living conditions of large sections of this population do not improve markedly, one cannot expect the IMR to decline below 40 per 1 000.

Coloureds

The improvement in life expectancy as well as the IMR are extrapolated from historic trends. Recent survey evidence indicates that the IMR of this group has decreased markedly over the past five years.

Indians

This group is rapidly gaining the same mortality experience as the white population.

Whites

Mortality trends of this group are assumed to continue, but will remain within the parameters of typical European populations.

Table 3: Life expectancy assumptions

	1990-95	1995-00	2000-05	2005-10	2010-15	2015-20
African (A)	64,8	67,3	70,6	72,5	73,7	74,5

Possible effect of AIDS

The present knowledge regarding HIV infection rates, the transition of HIV into full-blown AIDS and the resultant death rates in South Africa, is already substantial but not enough for demographers to accurately assess the effect AIDS has on the South African population. Internationally it is conceded that AIDS projections have to contend with many unknowns. Many projections border on doomsday prophecies, largely owing to inaccurate assumptions.

A number of factors could have a major effect on possible AIDS deaths in future:

- The possibility of an effective medical cure for AIDS.
- The success of information, education and communication (IEC) campaigns to counter risk behaviour in respect of AIDS. If these campaigns are successful the scenario of vast numbers of AIDS-related deaths will hopefully not materialise. One requirement for the success of such campaigns is a highly literate community which is able to understand what AIDS is and how to prevent it from spreading. It would appear that IEC campaigns in South Africa have been successful in so far as the majority of the population are aware of AIDS. However, the population has apparently not yet modified its behaviour accordingly.

In terms of this set of projections it is envisaged that present HIV infections will only start having a noticeable effect on mortality levels towards the end of the projection period. AIDS-related secondary illnesses, such as pneumonia and tuberculosis, could affect population growth at an even earlier stage.

Assumptions regarding international migration

Historically, international migration with regard to South Africa was balanced between two factors. On the one hand, there was an implicit desire by the government to strengthen the white population by white immigration. On the other hand, the number of immigrants had to correlate with the employment opportunities. Over the past decade the nett gain of immigrants has averaged 10 000 per annum. The reality of African international migration was ignored by everybody, including academics.

However, recent developments have made it imperative to take immigration into account when discussing population trends in South Africa. It has become apparent that for a long

time South Africa has been the destination of undocumented migrants. This process was facilitated by a number of factors:

- The contract worker system on the mines enables labourers from neighbouring countries to work in the country for a fixed period. One can assume that not all these workers return to their countries of origin upon completion of their contracts.
- A long border with neighbouring countries. It is impossible to create an impregnable border, as the experience on the Mozambique border has shown.
- The relative economic stagnation in Africa caused in part by the triad of war, famine and disease.

Important is the relative attractiveness of South Africa to immigrants from other African countries, as the economies of these countries are relatively underdeveloped. Estimates of the number of undocumented aliens differ widely, and figures between one and two million are mentioned. The demographic effect of large-scale immigration is considerable and two possible scenarios with regard to immigration were selected. No attempt was made to construct migration assumptions for the non-African populations since their demographic effect would be much smaller and would merely add to the number of possible projections, complicating matters.

Scenario A

Under conditions of continued economic growth it can be expected that South Africa will attract both skilled and unskilled workers. It is assumed that 100 000 immigrants will enter the country annually.

Scenario B

Two assumptions are made to illustrate the demographic impact of varying levels of international migration:

- 100 000 immigrants per annum
- 200 000 immigrants per annum.

Results of the projections

The results of the different population projections are summarised in Tables 5 and 6. (Annexure A contains summarised as well as detailed tables of the different sets of projections.)

By the year 2020 the difference between the optimistic lower fertility scenario and the less optimistic scenario will be about 7,8 million persons. Under the assumptions of Scenario A

the total population would number 65,7 million, whereas under the assumptions of Scenario B the total population would number 73,4 million.

Table 6 reflects the demographic impact of immigration on the population. Under the assumption of moderate to high immigration (100 000 per annum), the total population of Scenario A at the end of the projection period would be 3,7 million more than if there were no immigration. In the case of Scenario B where higher immigration is assumed (200 000 per annum), the total population would number 81,2 million persons, 7,8 million more than if there were no immigration.

Table 5: Projections – natural increase, 1990-2020 (in millions)

Urbanisation

Projecting the number of urban dwellers for the non-African groups produces results with a relatively small margin of error.

However, similar projections for the African population are subject to considerable variation. When analysing urbanisation patterns and trends in South Africa over the past four decades, it is clear that African urbanisation has not proceeded in a fashion similar to urbanisation among the other population subgroups. The primary reason for the slower rate among the African population was the various influx control mechanisms set in place mainly since the 1950s. Urban growth among Africans in the 1960s and 1970s was largely the result of natural increase rather than rural-urban migration. By the mid-1980s influx control was relaxed and the stream of rural migrants, especially to the metropolitan areas, grew. With regard to projections for Africans, a number of constraints exist:

- The relatively low level of urbanisation at present. The scope of estimates for future levels and patterns will therefore be more varied.
- Census information that is less than perfect in respect of historic as well as present data.

- A paucity of information regarding the TBVC states.
- Perhaps the most serious problem facing the analyst is the definition of "urban". Using 1985 data, Lucas (1990) estimated the urbanisation level of the African population in the RSA (excluding TBVC states) at 79,5 per cent, compared with 42,3 per cent using the conventional definition. The Urban Foundation (1993) estimated the urbanisation level for the same year at 53 per cent. (See also Graaff, 1986 and Calitz, 1994.)
- Reclassification in future of rural localities will have a major impact on urbanisation levels.

At present a number of processes are at work, resulting in differential patterns with implications for estimates of future levels and trends:

- The growth of urban centres in the predominantly rural homelands and TBVC states tied primarily to the growth in the regional bureaucracies.
- The growth of dense settlements in African rural areas. These settlements are usually not dependent on agriculture as most households are dependent on income derived from migrants or commuters.
- The vexing question of circular migration. A large number of persons from predominantly African rural areas are away from home for a considerable period of time for employment reasons. In Venda, for example, 30 per cent of males in the age group 25-44 are absent for this reason.

Future African urbanisation: General remarks

To estimate future levels of African urbanisation, different exploratory techniques were employed:

- The United Nations (1987) method for projecting urbanisation levels. This method uses a logistical equation derived from the observed difference between the rates of urban and rural population growth. Applying the method to the African population, an urbanisation level of 56 per cent in 2020 was obtained, compared to the present level of 38 per cent. This projected level seems too low, as the method is sensitive to observed rates and any inaccuracies will lead to spurious results. As an experiment, the urban growth rate was assumed to remain constant at 5 per cent per annum while the rural population was held constant, resulting in a projected urbanisation level of 76 per cent. However, these projected growth rates were based on conjecture and have no foundation.
- As an alternative, it was assumed that the present rural population has reached its zenith and any future additions to this population will become urbanised. The results thus obtained showed an urbanisation level of 66,8 per cent in 2020 in respect of Scenario A and 71 per cent in respect of Scenario B. It is an attractive way of dealing with the problem, as the method is based on an assumption that can be defended – rural areas do

not have the capacity to absorb their own natural increase. This may still be a lower estimate of future urbanisation since certain areas classified as rural at present may at some stage be reclassified as urban. On the other hand, land redistribution in future could have the opposite effect, by keeping more people in rural areas.

The population was broken down into the following segments: metropolitan, larger urban areas, smaller towns, rural communities and closer settlements. Because “metropolitan” is a different concept than urban, and tables will not add up if a general “urban” category is employed, the approach to the problem at hand was consequently adjusted.

Faced with a number of near insurmountable methodological problems with regard to the prediction of future urbanisation, it was decided to follow the procedure adopted in the main set of population projections, which can be described as an “If ... then” *modus operandi*.

General assumptions with regard to future African urbanisation

- The movement of the population to metropolitan and other urban areas can be expected to continue.
- The rural population will probably not increase and could even lose significant numbers.
- Urban “growth” by redefining certain semi- or peri-urban areas will play an important role
- Since the base population in this report is larger than the official figures, it was assumed that the majority of these persons are resident in metropolitan or urban areas.

Assumptions: Greater metropolitan areas

Metropolitan areas are a spatial concept which embraces a combination of settlement patterns, for example cities, towns, semi-urban, peri-urban, squatters, farms and black rural. Greater metropolitan areas, as focus points of economic growth, can expect high rates of in-migration and natural growth in future.

The four metropolitan areas are defined as the

- PWV (Gauteng) area, including the Bophuthatswana districts of Odi and Moretele and KwaNdebele
- Durban/Pietermaritzburg area, including the surrounding KwaZulu districts
- Cape metropolitan area
- Port Elizabeth/Uitenhage area.

In 1991, 66 per cent of the white population, 55,7 per cent of the Coloured population and 90 per cent of the Indian population were resident in the four greater metropolitan areas. For these groups, assumed saturation ceilings form the basis of the assumptions.

In the case of the African population it was decided to use the levels and trends of the non-African population with regard to metropolitan settlement as an analogy for estimation purposes. At present about 37,4 per cent of the African population are resident in these four complexes. If the ratio of metropolitan population to total population reaches 55 per cent in 2020 (approximately the present level of the Coloured population), then the metropolitan areas will have the population sizes depicted in Table 7. It is assumed that initial growth rates could be as high as 4 to 5 per cent per annum, tapering off later in the projection period. The experience in developing countries confirms an explosive phase followed by lower growth rates.

The level of in-migration to these four areas by persons in search of employment and housing may present a serious barrier to the envisaged development plans in these areas.

Table 7: Estimated population of the greater metropolitan areas, 1990-2020 (in millions)

	1990	1995	2000	2005	2010	2015	2020
African (A)	9,53	12,44	15,53	18,80	22,09	25,78	29,85

Indian	0,86	0,91	0,97	1,02	1,07	1,11	1,14
White	3,32	3,40	3,49	3,56	3,60	3,62	3,61
Total (A)	15,52	18,75	22,19	25,77	29,33	33,29	37,59
Total (B)	15,52	18,80	22,36	26,33	30,77	36,00	41,86

"Second-order" urban areas

It can be assumed that secondary urban centres will experience future growth, but at a somewhat lower rate than major metropolitan areas, since in all probability such towns and cities will be perceived as less attractive destinations by prospective migrants.

The list of cities or major towns included in the list of "second-order" urban areas are:

George, Kimberley, East London/Mdantsane, Grahamstown, King William's Town/Bisho/Zwelitsha, Bloemfontein/Botshabelo, Welkom/Odendaalsrus/Virginia, Bethlehem, Kroonstad, Potchefstroom, Klerksdorp, Rustenburg, Witbank, Middelburg, Bethal, Secunda, Ermelo, Nelspruit, Pietersburg/Sheshego, Newcastle/Osizweni/Madadeni, Richards Bay/Empangeni, Ladysmith/Ezakheni and Mmabatho.

In Table 8 future estimates are made for the second-order urban areas. The share of the population of these centres with regard to the total population was projected, taking into account present levels, and using the patterns of the non-African groups as an analogy for future African trends. At present 7,4 per cent of the African, 7,9 per cent of the Coloured and

15,4 per cent of the white population are resident in second-order urban areas. The white population is not expected to grow substantially since the source of population growth is more or less expended (low natural increase and a small rural or town population). In the case of the African population it is assumed the share of this segment could increase to 13 per cent of the population by 2020.

Table 8: Estimated population of “second-order” towns and cities, 1990-2020 (in millions)

	1990	1995	2000	2005	2010	2015	2020
African (A)	2,20	2,80	3,55	4,35	5,17	6,09	7,06
African (B)	2,20	2,81	3,59	4,48	5,51	6,73	8,06
Coloured	0,26	0,30	0,35	0,41	0,46	0,51	0,57

White	0,78	0,81	0,82	0,84	0,85	0,86	0,86
Total (A)	3,56	3,95	4,76	5,64	6,53	7,51	8,54
Total (B)	3,56	3,96	4,80	5,77	6,87	8,15	9,54

“Third-order” urban areas

The “third-order” urban areas comprise the urban population not included in the metropolitan areas or in the second-order urban centres. In 1990, about 6,8 per cent of the African population, 23,1 per cent of the Coloured and 12,1 per cent of the white population were resident in this segment. There is a potential for significant growth, taking into account the future effect of reclassification of rural areas (semi-urban or peri-urban) as urban. It is assumed that the share of the African population classified in this segment could reach 12 per cent by 2020.

Table 9: Estimated population of “third-order” urban areas, 1990-2020 (in millions)

	1990	1995	2000	2005	2010	2015	2020
African (A)	2,03	2,59	3,24	4,01	4,80	5,59	6,51

Total (A)	3,45	4,05	4,74	5,53	6,33	7,12	8,02
Total (B)	3,45	4,07	4,78	5,65	6,64	7,71	8,95

Rural population

In this report “rural” is seen as a function of urbanisation. The rural population is derived by the difference between the total population and that of the metropolitan, second-order and third-order urban areas. In the case of the non-African population groups, the share of the rural to total population will decrease in future, more so in the case of Coloureds. The white and Indian groups have already reached very low rural levels.

For the African population, an implicit assumption was that the rural population will cease to grow and in time experience a negative growth rate, due to out-migration or reclassification. If the population trends of the other groups are taken into account, the derived rural population of 20% in 2020 is not unrealistic.

Table 10: Estimated population of rural areas (excluding metropolitan complexes), 1990-2020 (in millions)

	1990	1995	2000	2005	2010	2015	2020
African (A)	15,92	15,89	15,83	15,47	14,54	12,89	10,86
African (B)	15,92	15,94	16,01	15,94	15,49	14,25	12,41

Total (A)	16,72	16,71	16,64	16,26	15,30	13,61	11,53
Total (B)	16,72	16,76	16,82	16,73	16,25	14,97	13,08

Rural African population

A division was made between the African population in white farming areas, black rural areas and closer settlements. As a first step the African rural population was split between “white farming” and African rural. It is assumed the African population in white farming areas will decline from 3,39 million to 2,80 million by 2020. This figure could be an overestimation of the African population in white farming areas, but redistribution of land could have a counter-effect. The population in African rural areas was derived by subtracting the population in white farming areas from the total rural population (see Table 11).

Table 11: Estimated African population of rural areas, split between “white farming areas” and African rural, 1990-2020 (in millions)

	1990	1995	2000	2005	2010	2015	2020
Scenario A							
“White areas”	3,39	3,29	3,19	3,10	3,00	2,90	2,80
African rural	12,53	12,61	12,64	12,31	11,54	9,99	8,06
TOTAL (A)	15,92	15,89	15,83	15,47	14,54	12,89	10,86
Scenario B							
“White areas”	3,39	3,29	3,19	3,10	3,00	2,90	2,80
African rural	12,53	12,65	12,82	12,84	12,49	11,35	9,61
TOTAL (B)	15,92	15,94	16,01	15,94	15,49	14,25	12,41

It should be kept in mind that a number of “closer settlements” were included in the metropolitan areas. The inclusion of such settlements in this report presents a number of problems. Closer settlements have been described as agglomerations of mainly informal dwellings, primarily in African rural areas, where the economic base is not agriculture. Households commute to work, or are dependent on remittances of migrant household members, pensions, and so on. However, it is not exactly clear what constitutes “closer settlements”. The Urban Foundation (1993) seems to have emphasised those areas within a

commuting distance to major urban areas, whereas Lucas (1990) included them even in deep rural areas. With the information at the author's disposal it was not possible to identify such settlements.

In future many closer settlements will probably be included in the "third-order" urban segment by reclassification. It is also certain that a core population, numbering several million, will remain in the African rural areas, be it in villages, betterment schemes or dispersed households.

Of note is the fact that Lucas (1990) classified the proportion of semi-urban Africans as follows (urban in brackets): KwaZulu 66,4 per cent (24,9%), Qwaqwa 88,4 per cent (11,6%), Gazankulu 89,8 per cent (4,1%), Lebowa 83,7 per cent (6,4%) and Kangwane 82,4 per cent (13,8%). According to his definition, between 90 and 100 per cent of the population fall into the combined category of semi-urban and urban. Although one need not accept his definition of urban, the figures do indicate the concentration and densification of population in the African rural areas. If the arguments of Lucas are accepted it would mean that at least 90 per cent of the population in rural areas are semi-urban, or even living in closer settlements. Simkins (Urban Foundation, 1993) created a category "closer settlements" and estimated the number of persons resident in these areas at 1,9 million in 1985 and 2,0 million in 1990. He stated that this category would increase to 3,9 million in 2010. However, there is a strong possibility that a fair amount of these persons were included in this study in the category "greater metropolitan areas". Without a specific definition of what a closer settlement is, and without detailed information regarding their location and size, it is recommended that this category not be included.

Number of households

In South Africa a historical record of headship rates and household formation is inadequate. To be able to project the formation of households by the ratio method, such information is required.

An alternative would be to employ average household sizes, in order to calculate the future number of households. In this exercise it was assumed that average household sizes will decrease over time (see Tables 12-16).

Table 12: Estimated total number of households, 1990-2020 (in millions)

	1990	1995	2000	2005	2010	2015	2020

Note:

Information from census sources regarding households, such as their number, composition and size, is probably not correct. During the adjustment procedures for the 1991 census no provision was made to adjust for households. If the general adjustment weights are employed to adjust households, one may assume that underenumeration only occurred as a result of missing households. One also has to assume that the size of missing households is the same as the average household size enumerated. Household sizes could consequently have been overestimated, since one source of missing persons in a census is non-enumeration within a household. One could also argue, for instance, that many squatters and backyard dwellers were missed as categories of households, where the average household size is smaller than other dwelling types. The number of households could therefore have been underestimated. However, as a macroplanning tool, this method gives the planner a very good idea of the probable number of households involved.
